Paper ID MD 15

REVIEW ON LEAN MANUFACTURING TECHNIQUES

Abstract

Lean manufacturing was developed for maximize the resource utilization through minimization of waste. Any industry whether manufacturing or service oriented to survive may ultimately depend on its ability to systematically and continuously respond to these changes for enhancing the product value. Therefore value adding process is necessary to achieve this perfection; hence implementing a lean manufacturing system is becoming a core competency for any type of organizations to sustain. The lean tools like Value Stream Mapping (VSM),Cellular Manufacturing (CM), U-line system, Line Balancing, Inventory control, Single Minute Exchange of Dies (SMED), Pull System, Kanban, Production Levelling etc is reviewed. In this paper, an attempt has to review lean techniques.

Introduction

Lean concepts are mostly evolved from Japanese industries especially from Toyota The term lean production was first used by Krafcik (1988) and it was drawn from the famous book titled The Machine that Changed the World: The Story of Lean Production (Womack et al., 1990). Lean manufacturing is flexible manufacturing techniques. It is very use full techniques for reduce the flow of non value added time. Lean manufacturing is a philosophy to reduce the time between customer order and products are ready for the delivery by eliminating waste.

What is lean manufacturing? Lean manufacturing is a system that integrate the daily work of producing and delivering products, services, and information of the problem identification and process improvement to eliminate waste and reduce production lot sizes.[1] The main aim of Lean manufacturing is the high quality, low cost, and just in time delivery by shortening the production flow by eliminating waste. Lean manufacturing is a team base structure. It breaks down organizational barrier and develops highly trained and motivated employees who investigate problems and find solutions as a part of their job. [1]

Tools of Lean Manufacturing Value stream mapping (VSM)

Value Stream is defined as "the set of all the specific actions required to bring a specific product through the three critical management tasks of any business: Problem Solving, Information Management and Physical Transformation". Value Stream Mapping (VSM) is the process of mapping the material and information flows required to coordinate the activities performed by manufacturers, suppliers and distributors to deliver products to customers. Initially a current state map was drawn from which the source of waste identified and its finds the opportunity for implementing various lean techniques. Rother et al [2] suggest that the Visual representation of VSM facilitates the identification of the value-adding activities in a Value Stream and elimination of the non-value adding activities. A second step in VSM is to draw a future state map based on improvement plan. The availability of the information in the VSM facilitates and validates the decision to implement lean tool and can also motivate the organization during the actual implementation in order to obtain the desired results. VSM clearly indicate the inventory, process time, Lead time, waiting time, etc and process flow from which we can sort out bottleneck cycle time against Takt time. Fawaz et al. case study investigate the "before" and "after" scenarios, through simulation which helps to illustrate the potential benefits such as reduced production lead-time and lower work-in-process inventory. Fawaz et al. [3] concluded that simulation model can be used to evaluate basic performance measures before lean implementation. The systematic continuous improvement starts with the bottleneck area. The prediction of levels throughout the production process is usually impossible with only a future state map, because with a static model one cannot observe how inventory levels will vary for different scenarios, so simulation tool is necessary for predicting the inventory level during demand uncertainty [4]

Takt time

Takt time refers to the frequency of a part or component must be produced to meet customers' demand. Takt time depends on monthly production demand, if the demand increases the Takt time decreases, if the demand decreases the Takt time increases which mean the output interval increases or decreases. Rahani et al. [5] Suggested that the importance of measuring Takt time due to the costs and inefficiency factors in producing ahead of demand, which includes Storage and retrieval of finished goods, Premature purchasing of raw materials, Premature spending on wages, the cost of missed opportunities to produce other goods, Capital costs for excess capacity.

Bottleneck process

Bottleneck process/constrain in the line is identified by determining the maximum cycle time in the line. The line/ plant capacity is decided by this bottleneck cycle time. Line Capacity is the product of Bottleneck Cycle time(C/T) and Total Available time, If Bottleneck C/T <Takt time, then Customer demand met, If Bottleneck C/T >Takt time, and then Customer demand is not met. With the past projected production delivery or from the expected future demand, the takt time is identified for the manufacturing system. With the known Takt time the bottleneck process are identified from the Value stream mapping (VSM), the gap between the capacity and demand is calculated and based on this gap the lean implementation plan is executed [5].

Group Technology

Shunk et al. [6] suggested that the successful implementation of flexible manufacturing system need grouping of parts using similarity among the design and manufacturing attribute which make the production plan and manufacturing process flexible. Based on the grouping of parts through similar process, dissimilar machines are grouped together to form a cell concept as suggest by lean concept. Cell formation is purely based on the nature of the process which varies from organization to organization.

Cellular manufacturing (CM)

Cellular Manufacturing is the grouping of miscellaneous equipment to manufacture the family of parts [7]. VSM provide route map for every part family, based on the route map the dissimilar machine are grouped together to form a cell. Wemmerlov et al. [8] suggest those dissimilar machines are clustered in sequential manner in order to meet process need of a family of product. Metternich et al. [9] suggested that the effective and efficient clustering of machine or cell is improved by moving employees, Workstations, or both into a U-shaped line which improve the employees' interaction. CM inducing multi skill process knowledge through implementing U-shape manufacturing line, many of the research and literature survey suggest that the U-line manufacturing is special type of Cellular Manufacturing system which improves flexibility in manufacturing system [10]. The Cellular Manufacturing system success depends on the successful implementation of U-Line manufacturing system, Line balancing, and Flow manufacturing.

U-line manufacturing system

Monden et al. [11] in his overview the entrance and the exit of the U-line, are placed on the same position. A rather narrow U-shape is normally formed since both ends of the line are located narrowly together. U-shaped lines line reduces number of work station, improve line balancing, visibility, communication, quality, flexibility, material handling. Guerriero et al. [12] clearly define the line flexibility for stochastic U line system and suggested that when demand uncertainty occurs, U-line layout provides greater flexibility to increase or decrease the necessary number of workers. The performance of U Line was evaluated by minimum number of workstations, minimum work relatedness, and minimum workload smoothness. Virtually U-line flexibility is interrupted by line imbalance in mixed model production line. In order to overcome this imbalance clear investigation of both balancing and sequencing task to be carry out simultaneously. The line imbalance is overcome by implementing line balancing and production flow.

Line balancing

Monden et al. [11] suggested that the consideration of task time variability is due to human factors or various disruptions which leads to U-line balancing problem. The task time variability is mainly due to the instability of humans with respect to work rate, skill and motivation as well as the failure sensitivity of complex processes. Becker et al. [13] and Chiang et al. [14] suggested task itself a sources of variability and explains the worker performing the task, and the environment where the task is performed. These sources of variability are

Proceedings of Conference On Insights in mechanical Engineering (IME-19) In Association with Novateur Publications IJIERT-ISSN No: 2394-3696 ISBN. No. 978-93-87901-04-9 March, 1st March 2019

controlled by minimizing the moving cost of men and machine. The operator walking time and fluctuation of man and machine cycle time leads to line imbalance. Also the change over time creates imbalance in the line for mixed model line which is necessary for lean. Based on demand, the number of worker and machine within the workstation are increased or decreased in order to overcome the line imbalance. Man-machine flexibility is achieved through free flow of material and information in the manufacturing process [11].

Flow Manufacturing

The principle of flow manufacturing is producing an item at a time at a rate equal to the cycle time, the successful implementation of flow manufacturing needs U-line layout, multi-skill operator, standardized cycle time, designing operator work as standing and walking manner and the equipment/machine should be standard and less expensive user friendly. Miltenburg et al. [15] Suggested that the break-through or tedious process flow can be balanced by introducing the customized machine in the workstation in order to balance the machine with the workstation cycle time [15]. The mixed model flow is smoothened by designing the workstation with Quick changeover and Small lot size.

Quick Changeover/Single Minute Exchange of Die

The quick change over time was introduced and developed by Shingo [16] which is popularly called as Single Minute Exchange of Dies (SMED).Based on time/video study Shingo separated the changeover (C/O) time into internal and external upset time. The activities performed by stopping the machine are called internal set-up time and the other hand the activity are performed without stopping the machine, these activity are called external set-up time. Yamazumi chart is used to analyze the internal (on-line activity) and external (off-line) set-up time. Based on these analysis possible internal set-up time are converted to external set-up and internal set-up time are streamlined by introducing multi operator working parallel during On-line activity and one touch set-up adjustments to convert the C/O time to single minute. Finally the sustainability of these set-up time improvements is achieved by standardization. Shingo [16] proposed rules for standardization of set-up time and they are Visualizations and standardization rule for overcoming adjustment and trial run and Machine with multiple productions tooling system. One of the critical task in C/O is setting parameter for first good product during initial trial run after C/O. The first good product setting parameter for initial trial run can be achieved using Taguchi experimental design .As a result of the Taguchi experimental design the trials needed to start mass production is reduced and also it reduces the wastage of material during initial production phase. The factors that affect the decision-making process of SMED are cost, energy, facility layout, safety, life, quality and maintenance. Almomani et al. [17] research on Multiple Criteria Decision- Making Techniques (MCDM) and provide a systematic procedure for selecting the best setup techniques such as Analytical Hierarchal Process (AHP), Preference Selection Index (PSI) and Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) by considering the above factors. The integration of MCDM with SMED leads to greater system flexibility and increase the productivity. C/O time play vital role in sequencing the batch in cellular manufacturing. Cheng et al. [23] suggest that the make span of the part family in cellular manufacturing depends on set up time [18].

Small Lot size/Small Batch

A batch is a set of parts of the same part family. While part families are supposed to be given in advance, lot sizing is a part of the decision making process. Conventional manufacturing systems are run based on buffer production system. The built-in buffer system was introduced to overcome the material flow interruption in case of for equipment break down, machine C/O, absenteeism which lead to high quality problem and lead time. In order to smoothen the material flow and to overcome the quality and lead time issues, buffer quantity should be optimized. In practice, Lean is associated with zero inventories to increase the visibility of product flows and optimize the utilization of capacity [19].

Inventory

Survey from various articles indicates that 60% of wastes in manufacturing system are due to inventory. These Inventories are classified into Raw material (RM), Work-in-process (WIP), Finished goods (FG). Increase in inventory of RM, WIP or FG leads to less inventory turnover. Inventory plays a vital role in firm's turnover, detailed literature from 1000 world class manufacturing firms revealed that 34% firms try to increase inventory turnover for at least 10 years [20]. Sakakibara et al. [21] suggested that the excess RM is due to poor projection of product plan, availability of raw material, defective parts, waiting for processing leads to more

Proceedings of Conference On Insights in mechanical Engineering (IME-19) In Association with Novateur Publications IJIERT-ISSN No: 2394-3696 ISBN. No. 978-93-87901-04-9 March, 1st March 2019

WIP, and unnecessary transportation between working stations or plants increases WIP inventory, overproduction of parts beyond the plan leads to FG inventories which wait long time in the warehouse or might never be sold. Inventories are reduced by improving the quality levels, rejection rates, delivery rate, lead time and customer satisfaction. RM is controlled by ordering material against the demand or ordered only after the design is accepted by the customer in case of new product. Demete et al. [22] suggested that WIP is controlled by implementing cellular manufacturing/dedicated line Assemble or manufacture the parts against the customer order reduces FG which means FG goes to customer without unusual delay. Imperfection due to lack of process control in the manufacturing system creates the WIP requirement in workstation. In order to reduce the impact adjacent process, the decoupling buffers is placed between processes to overcome the imperfection. The buffers allow each of the teams to make decisions regarding stopping the line to fix problems. Buffer violates the lean system but in practice safety buffer is necessary in case of system fluctuation. If certain workstation run worse than others and the buffers are stripped, individual workstation can run overtime in order to build backup the inventory. As a result manufacturing lead time increase which in turn increase the WIP. Kanban and Pull system are the lean elements that control the WIP.

Pull System with One-Piece Flow

The Pull system enables the production based on customer demand; the downstream process/customer takes the product/service they need and 'pulls' it from the producer. Smalley et al. classify the pull as replenishment pull, sequential pull, and mixed pull system. The successful pull system depends on flowing product in small batches (approaching one piece flow where possible), pacing the processes to takt time (to stop overproduction), and Signaling replenishment via a Kanban signal and leveling of product mix and quantity over time .One-Piece Flow refers to the concept of moving one part at a time between operations within a cell. One- Piece Flow production system consider factor such as sequencing, setup time and make-to-order policy, therefore consideration to be given to those factor during scheduling of production. Stockton et al. [23] Designed the operator walk cycles for an existing one-piece flow flexible manpower line, in which operators were allocated a repetitive sequence to load and unload machine tools. Their flexible manpower line was essentially flow process line where the machines were arranged in U-line. Work model selections, operation assignment to U-line and production sequence are the important factor to be considered while designing the one-piece flow. In U-line when Change over task or other task takes place, the whole production line is disrupted in such a case buffer is permitted in One-Piece Flow based on requirement in order to overcome these issues. In one-piece pull production system, the producer begins the production when a user shows the Kanban card/signal for parts. Li et al. [25] suggested that the design of uncertainty based one-piece flow need multi objective evaluation; also develop the fuzzy ant colony Optimization model for evaluating the multiobjective task to minimize cycle time, changeover count, cell load variation and the number of cells [24]. The study and survey in the area of one-piece flow is limited.

Kanban

Kanban is a subsystem of the Lean manufacturing system which was created to control inventory levels, the production and supply of components. Junior et al. [26] suggest that with the knowledge in the creation and accumulation of Kanban system, the implementer can classify, and analyze the variations of the Kanban. Sipper et al. [27] Classify the Kanban system into the dual card Kanban system for signaling production and transportation Kanban system for signaling. During demand uncertainty the buffer maintenance is necessary for smoothening production flow and reconfigures the Kanban System in order to lower the inventory. Thus Kanban system provide mixed model production along with optimal inventory level which results in less lead time in product delivery and effective utilization of resources such as man, machine etc.

Production Leveling/ Heijunka

Current business environment are volatile which leads to fluctuation in customer demand, this fluctuation leads to variability in the production. In order to overcome this fluctuation initially leveling of customer demand is necessary, Without leveling, this fluctuation leads to underutilized capacities such as man and machine idle times or quality problems, breakdowns, and defects (in case of overburdened capacities) [28]. Bohnen et al. [29] suggested that the leveling low volume and high mix production based on the principles of Group Technology is necessary for fluctuating customer demand. Bohnen et al. develop the cluster technique for part family formation and family oriented leveling pattern for implementing low volume, and high mix production system. The Balanced work load in production is achieved through Every Part Every Interval

Proceedings of Conference On Insights in mechanical Engineering (IME-19) In Association with Novateur Publications IJIERT-ISSN No: 2394-3696 ISBN. No. 978-93-87901-04-9 March, 1st March 2019

Concept (EPEI) leveling pattern which is formed based on product families, According to EPEI every product type is manufactured within a periodic interval. The concept of Heijunka is to control the variability of the job arrival sequence to permit higher capacity utilization, also it avoid peaks and valleys in the production schedule [29][30]

Quality at source

In lean manufacturing system the lot size is reduced to one piece. In one-piece flow the part are conveyed, processed and inspected one at time, as a result the random inspection of lot samples or lot-based statistical quality control methods is eliminated. When a defect occurs, immediately the production line is stopped until the cause is eliminated. False-proofing/ Poka Yoke is incorporated with production line to prevent/detect the error occurrences. In case of detection the line must be stopped until the cause is eliminated. In such case the line is equipped with Automation/Jidoka (automation with human touch) which has the ability to stop line when process goes wrong. The quality problems in the operation of automated equipment are due to human errors in loading, unloading and setup. Among these error priority is given to setup errors because it create quality problems for the more number of products. To achieve the highest levels of quality, the setup, loading, and unloading must be False-Proofed. Implementation of False-Proofing improves the quality standard and reduces the operator inspection time. [13][31]

Continuous Improvement (CI)/Kaizen

Continuous Improvement (CI) is a philosophy that Deming described simply as "Improvement initiatives that increase successes and reduce failures" Continuous Improvement is the management driven element which effort the cultural change in the workplace. Once process stability is established, CI element tools are required to determine the root cause of inefficiencies and apply effective countermeasures to reduce those inefficiencies. Establish and design a process with zero inventories exposes waste such as the idle time, waiting time, inventory and resource problem. In order to eliminate this waste, management need to develop the stable personnel with organization knowledge base. Berger et al. [32] overviews that Continuous Improvement is based on a belief in people's inherent desire for quality and worth, and management has to believe that it is going to "pay" in the long run. In this competitive environment CI is necessary for sustaining in the market, but the success of the Continuous improvement depends on employee perception, adaptation, team work, leader engagement, motivation, initiative, and training. CI mechanism include training problem, process problem solving, training CI tools and technique, development of idea management and development of reward and recognition system. [33][34] [35][36]

Standardized Work

Berger at al. [32] suggested that the Standard Work is the basic tool for continuous improvement. . Standard Work refers to the safest and most effective method to carry out a job in the shortest repeatable time as a result the utilization of resources such as people, machines, and material is effective. Work Standardization can be described as a set of analysis tools that result in a set of Standard Operating Procedures (SOPs). SOP contain operator work process such as process steps, work sequences, cycle time, work-in-process, process control etc., SOPs represent the best thinking on how to do a particular job within the target time. Once Standardized work is established, it is possible to control and improve work design with respect to demand with slow-downs or speed-ups in work. Standardized Work helps in reorganizing the work with respect to Takt time fluctuation; with demand increases we can incrementally add workers. If demand decreases, we can incrementally remove workers from the assembly line [37][32]. Monden in 1983 introduced Standardized Work Chart (SWC), Standardized Work Combination Table (SWCT) and Standard Operation Sheet (SOS) are useful for analyzing and improving the standardized work. The SWC Visualizes operator movement and material location in relation to the machine and overall process layout.SOS describes the operator The SWCT Visualizes the combination of manual work time, walk time, and machine processing time for each operation in a production sequence. The purpose of SWCT is to identify the waste such as WIP, waiting and overburden of work. Finally, the work instruction of the operation is described by SOS [13].

Incorporation and sequencing of lean elements with dependent elements are the vital factor for the successful implementation of lean manufacturing system as suggested by most of the survey. In this survey, a lean road map is proposed for implementation of lean elements along with other interdependent elements. Steps in implementing the Lean elements are as follows VSM for analyzing the capacity and Takt time to identify the production gap, based on this gap, implementation goal is proposed. Second step is implementation of Group

Proceedings of Conference On Insights in mechanical Engineering (IME-19) In Association with Novateur Publications IJIERT-ISSN No: 2394-3696 ISBN. No. 978-93-87901-04-9 March, 1st March 2019

Technology; here parts are grouped into part family and machines are grouped based on these part family. The third step is implementation of Cellular Manufacturing. Cell formation depends on group technology and part family VSM along with successful implementation of U-line system and Flow Manufacturing, further U-line system is streamline through Line Balancing and material/information flow is streamline through Flow manufacturing. The successful implementation of Flow Manufacturing depends on SMED and Lot size reduction which stream line RM, FG and WIP. The fourth step is implementation of One-Piece Flow Pull System which depends on all the above elements. The fifth step is quality control at source, which depends on implementation of False-Proofing and Automation. The sixth step is implementation of this element depends on successful implementation of all the above said elements. The eighth step is simultaneous Standardization and Continuous Improvement. Finally EPEI concept should be implemented to satisfy Every Customer in Every Interval. In order to sustain in the competitive market eighth step should be repeated.

Conclusion

The lean tools adopted by the manufacturing industry were compared to some of the lean tools adopted by the service sector or healthcare industry in particular and conclusions were made about why certain tools are more relevant to a certain industry. An integrated list of lean tools used in both the manufacturing firms and service sector was compiled and it was seen that TQM, JIT and human resource tools were the most used tools common to both sets of industries. Human Resource tools were seen to have a higher importance in the service sector as compared to the manufacturing sector. JIT tools were found to be equally popular in both the industries. During the literature review for this article it was found that there was a lack of data on the implementation of six sigma tools in the service sector, this could be an area of further research.
